"The Triple C's"- The Master Guide to Get Capital Gains Growth & Dividends in Any Market

This E-Guide about the "triple C's" is a total system of investing that I've honed over the last 10+ years that you can use daily.

This system can be the starting point for which any individual who wants to invest in the market and be financially free can do so, and then they should build upon

that with the 5 other complementary techniques mentioned in this Guide.

They will certainly help increase performance with the triple C's and add more weapons to your arsenal of investing.

This approach provides scalability relative to account size, and even though it is a slightly "unconventional" method, it is one of the best ways to get both dividends for qualifying income to the banks (for loans) AND day's gains.

Extra growth is what we so desperately need in order to offset the "decay" seen from the newer ETFs taking the world by storm, including Yieldmax, Defiance, RexShares, YieldBoost, and Roundhill, and this E-Guide aims to accomplish just that-

to supercharge the growth in your investment account.

Disclaimer- This IS NOT financial advice. I am just a man sharing information that I've accumulated over my 20-year investment career that allowed me to retire early at the age of 37.

Chapter 1.

What Are the Triple C's?

I've used the "triples" for over 10 years and they've worked like a charm, growing my account by leaps and bounds, especially after significant corrections have taken place in the market.

The "triples" are triple leveraged ETFs designed to do whatever the indexes do, up or down, X3.

These triples (UPRO, TQQQ, SPXL, UDOW, etc.) are the big money makers capable of earning you a million in a relatively short

amount of time, with only a small amount of capital used.

Just 20K invested for 10 years with UPRO and TQQQ, according to Morningstar, made you $1 million dollars. (see my old videos for those).

UPRO and SPXL track the S&P 500 while TQQQ tracks the Nasdaq. UDOW tracks the Dow Jones X3.

However, there is no qualifying income with the triples, as my banker told me when I tried to buy a new house for my son TJ, and so I had to get the highest "indexed yield" I could find.

Since our whole strategy is predicated on the indexes, that's where 4-star rated

Cornerstone (CLM & CRF, or the C's) came into play.

Combine the two vehicles together, the triples and the C's, and it makes for a potent combination of growth and yield.

Not only can you win big in these investment funds, but the odds of losing with this strategy are minimal, even with margin in a down market, and I'll show you how.

Chapter 2.

Why Build Your Portfolio Around the Triple C's?

Again, our entire investment strategy is based on the indexes because indexes like the S&P 500 average 7%-10% returns per year.

Indexes fall less than stocks by a wide margin in down markets, and eventually bounce back, unlike stocks- which fall harder and may never bounce back.

This is how I'm able to focus such a large amount of capital behind the triple C's and not only outperform in both up and down markets, but I can also sleep at night knowing my capital is concentrated in the safety of the indexes.

Concentrating larger amounts of money behind the indexes also helps with compounding, which is the 8th wonder of the world.

It's much easier to make $10,000 on $100,000, which is just 10%, whereas if you had only $10,000 invested in a stock for "more growth", then you would need a double to earn just $10,000 more.

Hitting a home run and doubling your position is extremely rare. As you know,

90% of fund managers can't beat the indexes over the long term.

Gordon Gekko once said to Bud Fox in the movie "Wall Street" that most fund managers can't beat the S&P 500 because they are sheep, and sheep get slaughtered. People are throwing darts at a board, and he bets on sure things.

A lightbulb went off in my head when he said that.

How can you assume outperformance of the indexes? ***Buy the indexes X3***. Hence where the triples entered the equation for me.

Even in down markets I've experienced since 08, the triples and the C's always bounced back.

I usually take trips at market highs because you have to cash in some and live off of your spoils.

Jesse Livermore, one of the greatest investors of all-time, thinks you should touch your money every so often to make it real. After all, we only live once, so what's the point of the money if we don't enjoy it?

Many market corrections have come while I was away on vacation enjoying my winnings, and the unique perspective I gained from those situations was invaluable.

For most people, it's easy to be timid in a down market and think the sky is falling. However, when you're traveling, you notice quickly that the world keeps

moving the same, even when in a "recession."

Even if some people lose their jobs in the recession, they still have to consume goods and survive.

70% of US GDP is consumer driven, to put things into proper perspective. So, even if people have to use their credit cards to survive, the majority of the economy still grows.

I noticed this phenomenon during the "Arab Spring" correction while in North Carolina for a Duke tournament, "Brexit" while I was in Milan, Italy (which was one of the PIGS nations: Portugal, Italy, Greece, Spain), and yet everything was operating "business as usual" there in Italy, even in debt-ridden Milan.

I used the triples to bounce back strong in all of these locations. In the correction of 2017-2018, my account fell hard while in the throes of Kowloon, Hong Kong, and it bounced back later that month in Tokyo, Japan.

Thanks to the triples, I went from 65K back up to my typical 100K barrier that I could never get past for years (until I found dividends, margin, and the C's).

During Corona I was at home, and I fell from 100K down to 15K.

Thankfully, I bounced back in those dreadful times, and made it to new highs in my account thanks to the triples, margin, AND the C's.

In 2022, I once again recovered all losses thanks to the triple C's, which I remember trading in Bozeman, Montana.

We were actually outperforming in that downturn thanks to the C's being dripped at the NAV, which buys the lows of the market FOR YOU.

We went to Europe again in 2023 and experienced yet another severe correction, which I covered on YouTube publicly for the world to see, and we bounced back strong there as well thanks to the triple C's on margin.

Lastly, we were home for the Trump tariff wars in 2025, and I traded my way through it successfully with my prized members, eventually outperforming ALL

OF THE INDEXES, even with over 50% margin leverage at the highs.

We had to deleverage, obviously, because the market fell too far too fast. But, we did so without ever having significant risk, or losing any permanent capital, and we bounced back even harder as a result, past $1 million, which I'll explain how in this E-Guide.

I just wanted to summarize how I got to this point in my life and investing career and, most importantly, I wanted to prove to you that the world keeps moving regardless of the media's portrayal of the economy.

So, those dips have to be bought every time in my opinion- and what are you

going to buy and build your portfolio around when the next correction comes?

The triple C’s.

Chapter 3.

Why The Triple C's Are Not Risky!

Not only do the triples always bounce back, but Cornerstone's dividend, alone, will cashflow you in 5 years due to receiving the 20% dividend over a period of 5 years (20 X 5= 100%).

When it comes to the triples, what's riskier?

Having $100,000 invested in a single leveraged, "safer" fund like SPY or VOO (The S&P 500)?

Or, having $30,000 invested in a triple leveraged “risky” ETF like UPRO?

Well, in a 50% crash, you would lose $50,000 invested SPY. But, in UPRO, the max you could lose is $30,000 (and you would never lose the entire $30,000 because the indexes never go to zero).

If the indexes did go to zero, investing is the least of our worries and we are back to bartering systems.

So, similar to a call option, which is risky in large amounts but safe in small amounts, you can only lose what you put up for investment in the triples, which would always be small relative to the size of your overall account.

Chapter 4.

Do The Triples Decay?

The triples are actually safer than most investments, but do they “decay”?

Decay, or price erosion, is a myth in my opinion when it comes to dividend stocks and triple long ETFs that are tied to the MAJOR indexes.

Yes, most triple leveraged ETFs decay badly on their charts and look nothing like their underlying holdings that they are designed to track.

See GUSH or HIBL, for example.

For those reasons, they should only be used as day-trading vehicles to take advantage of a particular uptrend you see forming.

However, the triples tied to the major indexes don't experience decay issues like the others.

Sure, they still erode, some. But, they typically make it back to old highs, and even to new highs, which is all I'm concerned about when trying to make money and compound my wealth.

Again, you saw that Morningstar chart in my videos. If $20,000 invested turns to around $1,000,000, then I'll take that "erosion" any day.

It’s the ETFs that don’t make it back to old highs, like GUSH, HIBL, or even TNA that you have to worry about, and you have to treat them as day-trading vehicles, only, as a result.

The triples can decay in down markets. But, that decay actually works for you in up markets, and helps you “melt up” or “compound up” daily in the process.

I remember one of the representatives from ProShares telling me this, which strengthened my conviction in UPRO and allowed me to increase my concentrations on the dips, with confidence, and sleep at night in the process.

Who wants to throw a good amount of their capital into something that may have big day’s gains, yes, but it falls

extremely hard in a down market as well, and never fully recovers, while the market marches to new highs?

That was the nightmare scenario for me.

No, I had to get to the bottom of this decay issue with the triples, since I was investing so much of my capital into them at the time.

I had to know they would rally back to their old highs, and then some, even if I never touched them again.

When I found out they did in fact typically make it back to old highs, that's when I knew I had something in the triples, and the world was wrong (as usual).

So, these broader-indexed triples are NOT created equal to other sector-specific triples that litter our investment landscape today.

Triples tied to the major indexes are a step-above the rest.

Chapter 5.

The Triple C's "Spreads" Save You!

The triples and the C's are some of the largest funds in the world and have better spreads than most!

No broker is actually commission free. Now, the real broker money is made from order flows. That means the broker gets a piece of the bid-ask spread difference.

The triples and the C's both have tighter spreads that help circumvent this problem, which is especially helpful in

down markets when everyone is panic-selling and spreads are getting blown out.

In many cases, the triple C's spreads are 3-4 cents, max, even in a down market. This is invaluable when buying and selling in larger lots, especially over $25,000.

The spread affects you no matter the position size. But, if the purchase amount you make is over $25,000, you can call your broker and get the spread negotiated down, one hedge fund manager told me at the Exchange ETF conference in Vegas.

This means, though, that you have to know what you're buying and selling for the day, and you need to have a clear plan so that you don't get caught off guard

buying and selling TOO much in a selloff. You don't want to annoy your broker, after all.

So, narrow your focus down to the triple C's in a market correction and read the rest of this Guide to deploy them correctly.

Again, these wider spreads in the lesser-known dividend funds like Yieldmax and Defiance can erode your account significantly.

Thankfully, you can avoid this problem with the triples. On the 90-day Trump concession rally, the triples (TQQQ and UPRO, for example) were the 4th largest ETFs traded that day, according to CNBC.

That gives you an idea of how big they are, and more importantly, how liquid they are.

Of course, if the management team behind the triples fail, then all bets are off.

However, they have made it through numerous corrections with flying colors, so I am willing to bet they have gotten stronger each time, with more AUM, and they have ironed out more kinks along the way in order to ensure their dominance in the ETF space.

Cornerstone (the C's), are also very liquid and are one of the largest closed end funds in the world, which no one talks about!

They've been around since the 80's and have proven the test of time. This stellar track record and liquidity advantage in Cornerstone is even more reason for you to focus your capital in the C's, along with the triples, when the opportunity arises.

So, welcome the next market correction with open arms so that you can apply this method.

In 10 years, and even 12 months later (historically speaking), you'll be thankful that you did.

Chapter 6.

The High Maintenance of The Triples is a Gift! Not A Curse!

Triples have high maintenance, yes, but that just informs you of their risk profile, which ultimately increases performance.

The higher maintenance MAKES you have to trim your core positions back to the original size in order to manage risk, and then you become a GREAT investor as a result.

(For help understanding maintenance, refer to my Vol. 3 E-Guide).

First of all, you can’t really raise maintenance much more on the triples and threaten a margin call with that high of maintenance, which at Etrade is 75%.

Other brokers may have lower maintenance. But, DON’T buy more triples just because you can preserve the equity at another broker.

In a down, or simply volatile/choppy sideways market, that erosion from an overweight position in the triples kills you.

YOU WANT TO TRIM the triples at the highs, back to the original position size, and then rebalance at the lows to offset decay/price erosion.

This kind of prudent portfolio management lowers both margin leverage and portfolio leverage, and helps you mitigate risk in the process.

Lowering your margin lowers your interest payments as well! This boost to the bottom line is always welcome because it gives me more money to spend and enjoy my daily life with.

Of course, you could always reinvest the savings from lower margin interest, which I did in the most pragmatic way, starting out.

I had to sacrifice material things that I enjoyed so much, and study teachings from the Bible even harder, in order to follow through on this plan to achieve F.I.R.E.

(F.I.R.E. Stands for financially independent retire early).

Chapter 7.

Respect The Power of the Triples Before Buying!

To go from theory to application in the triples, first you have to understand their power.

Having $100,000 invested in the triples, like UPRO, is akin to having $300,000 in SPY, after all.

So, with other dividend funds being invested into at the same time as the triples, WITH incremental margin usage, AND perhaps even naked puts on top of

that, it makes for extreme money-making abilities.

However, that combination also MAGNIFIES losses on down days.

Therefore, the sweet spot for triple long leveraged ETFs is:

10% of your portfolio in a bull market, which is approximately $100,000 on a $1 million dollar account.

Chapter 8.

How I Use UPRO To My Advantage in a Downturn- Without the Risk

(This is the longest and most important chapter, read slowly!)

Remember, on a $1 million dollar account, 10% invested in UPRO is $100,000, which is equivalent to $300,000 SPY.

We want to track the S&P 500 (SPY) at all costs.

But, we don't want TOO much SPY exposure, unless we are at the lows,

which is usually 10%-30%+ off of the old highs in my experience.

In 2008 the market fell around 50%, but that was a rare occasion, where the risk was systemic and financial collapse loomed throughout the world.

At around 10%-30% correction levels from the highs, I've used approximately $300,000 worth of triple leveraged ETFs ($100,000 every 10% down).

Members saw this during March of 2025.

Of course, that's like having $900,000 SPY exposure, which is essentially my entire $1 million account, obviously a very risky approach, exacerbated by the lack of dividends.

Keep in mind that I was comfortable using this much triple leverage exposure because I was more experienced than the average investor. However, there isn't really as much risk involved as you might think.

If my account ever falls more than a few hundred thousand in a downturn, let's say it falls even HALF in a 50% crash, then my account would be at about $500,000, and my margin leverage would still be there.

However, I could have completely sold out of DEFIANCE and Roundhill on the way down, which I had over $500,000 worth at the time, ***deleveraged completely (so the margin risk is gone), harvested the tax losses***, ***and bought 1/3 of the triples instead***, going with a

smaller amount of margin leverage than I was using before.

The only risk to this strategy is losing in the indexes, themselves, which is a risk I'm willing to take.

It's a bet that capitalism will survive, essentially, and that USA would remain at the helm.

If the market kept falling, I would have sold more income-paying funds and bought 1/3 the amount of the triples, again, reducing margin to zero.

When the market bounces, I would trim out from the triple longs in order to go back into those income-producing names, since we need income to survive flat

markets, and to provide qualifying income to banks for loans.

Remember, you can only lose what you put up in the triples, which is a small amount relative to your total portfolio size (10%-30% max), and you would never lose it all as the indexes don't go to zero (like an individual stock could).

So, when I sold $500,000 of those newer, higher yielding dividend funds like Defiance and Roundhill, I bought $175,000 worth of names like UPRO, instead, for the equivalent bounce back potential (all in positions of course).

You would want to employ this technique, even without margin, in my opinion. Here's an example in one of my SMS texts to members:

(Unconventional Wealth Ideas) “Trimmed 10K QDTE and bought 3K TQQQ”. STOP to end

FYI I issue these texts frequently as an additional benefit to members.

When the market turn-around is in full effect, which inevitably will occur, you will be making massive gains in the triples while still collecting income on the $500,000 worth of dividend funds that you never sold. Remember, I sold half of the $1 million in dividend funds, and left the other half for steady income to pay bills in a downturn.

So, after the rally, you would simply want to TRIM the triples back to the original core position you had of around 10%.

I had, and still have, about $100,000 worth of triples on in a $1 million dollar account, since I trimmed them back on the way up.

Every time my triples, collectively, rise to $105,000, I trim (not sell completely) $5,000 out to rebalance back to $100,000. I sell from one triple or another, depending on which one is up that day.

This helps lower concentration risk, beta leverage, and margin leverage- while raising precious available for withdrawal (AFW) at the same time.

Since the triples are such high maintenance at Etrade, when you sell them, it floods back the equity in a hurry, raising AFW in the process.

AFW is the lifeblood of your account, whether in margin or not. The higher the AFW, the more security you have against a margin call, you can withdraw to pay bills, and live FIRE.

When you trim them, you don't just stay on the sidelines. You immediately put that capital to work in the singles again (like Roundhill, Defiance, Cornerstone, etc.) to increase income and allow for more upside as the market recovers, albeit with less capital gains growth than you were accustomed to getting in the triples.

I'm ok with this tradeoff, as I'm in this game for dividends to live FIRE, with minimal risk, NOT to make day's gains to impress my friends. Again, you can't qualify for loans with day's gains, either.

Here is another example of this action to my SMS members:

(Unconventional Wealth Ideas)
"Trimming triples into the strength, as usual, and buying more Roundhill with the proceeds. Roundhill is a safe area to sell from in volatile markets, if need be, and then you can buy back after when things stabilize, which is what we are doing now." STOP to end

Roundhill is not a big mover, after all, like our triples are. So, ***with every other 1% up day or so in the markets,*** I trim the triple longs back to $100,000, and add the equivalent amount back into Cornerstone, Roundhill, RexShares, and Yieldmax (RDTE, QDTE, YMAX, YMAG, AIPI, FEPI, & ULTY).

After a 10% bounce back from the lows, I tend to trim the triple longs AND rebalance the triple shorts back to $1,500-$3,000 each.

At the absolute lows of the market, I had as much as $15,000 in each triple short, making for about $100,000 invested in triple shorts, total.

This move with the triple shorts neutralized my risk in the new triple longs purchased.

After all, when I had that “straddle” going (1:1 new triple longs to shorts), I would have won either way.

At the highs of the market, I had minimal amounts of the C’s, as you may well remember.

The 30% plus premiums in the C's were the sign to sell, even though we got the N-2 filing alert in Discord for those who didn't want to go by the premium levels found in my Volume 4 E-Guide.

So, again, we were mostly out of the C's at the highs.

As the market fell, I increased triple shorts for protection, AND I increased the triple C's, both in small amounts.

You can start with 10% as your base in the triple longs at the highs, as we mentioned (that's the sweet spot), and then with every new $10,000 deployed, long and short, this equal weighting of new capital in the triple longs and shorts

gave me, effectively, no risk on the way down from the highs.

Yet, I was guaranteed to win big one way or another. On one side, I would lose only the $10,000 invested. But the other side of the position long/short (either one) could have made potentially a million, long-term.

This is the benefit of straddles at, or near, the highs.

When the markets move to the lows, and are off at least 10% from the highs, I start to augment the straddle by going to a "strangle" (or 2:1 long to short in the triples), but always in small positions.

Every 1% down in the market, which is huge by the way, I added small to the

triple longs with the proceeds from trimming the triple shorts back to their original position size ($10,000-$15,000).

This way, we don't have to use margin to risk more losses should the market continue to head lower. Our triple shorts ***paid*** for the new triple long positions.

This is what naturally starts the "strangle" for us.

We let the position sizes and AFW dictate when to make these moves, not the media or some other YouTube channel.

You employ this strategy regardless of the influence of outside conditions.

On the way back up, you trim the triple longs, again, and redeploy into the single-leveraged dividend paying funds we mentioned above.

When these single-leveraged dividend funds (CRF, CLM, CHW, CSQ, EXG, ETV, GDV, BDJ, STK, YMAG, YMAX, QQQY, IWMY, QDTE, RDTE, WDTE, XDTE, IQQQ, QQQI, SPYT, XPAY, MAGY) have big enough moves up for you, you reverse the process by selling some of them, and buying back the equivalent 1/3 of the triple.

Here is another SMS text example to my members:

(Unconventional Wealth Ideas) Sold $5K MAGY for the gain and switched to $1.5K FNGB. Since MAGY hasn't paid a div yet, it

doesn't affect current income. This move lowers overlap risk with FANG and raises AFW in the process. Still have YMAG of course (100K).

Every 10% up or so in the market itself (SPY), rebalance the triple shorts with the proceeds from trimming the triple longs.

I keep those short positions small (1%-5% of the total portfolio) so that I'm not just throwing capital away in the shorts. They are an asset that's designed to lose overtime, unlike with the triple longs, which typically move up to new highs over time.

You will be taking substantial profits at the lows in the triple shorts when you start your strangle, and moderate losses

at the highs as the market climbs back and you unwind them, and that's ok.

First of all, you can write off those short losses. Secondly, we aren't trying to profit on this triple short strategy in a ***major way, leave that to our put options.***

We only want the triple longs and our country to comeback, making us prosperous again.

The triple shorts act more as a vehicle to neutralize risk into the downturn, and ease your mindset in order to keep your triple longs on with conviction.

If you time the triple shorts perfectly, sure, you can maximize your profits on both the long and the short side.

However, again, I really just want my long side of the portfolio to comeback strong, and the shorts to allow me to stay relaxed enough in order to do so.

I only used 5%-10% of my account with the triple shorts when market volatility was at peak heights, and substantial margin leverage was still on.

Chapter 9.

5 More Techniques to Maximize the Triple C's

1.) Keep some inverse triple shorts on at all times, as we mentioned earlier.

1% minimum for me, and then I increase to 2-3% when the market tops out.

I can go as much as 5-10% triple shorts in order to straddle the new triple longs that I'm buying on dips (on the way to down) just to protect myself from an unexpected fall-off, if we have already corrected 10%-30% from the highs.

Use: SPXU & SPXS to hedge SPXL and UPRO, SQQQ to hedge TQQQ, SDOW to hedge UDOW, SOXS to hedge SOXL, and FNGD to hedge FNGU/FNGA/FNGB.

If/when triple longs are over 10% of your portfolio, and the markets are crashing, keep 5%-10%+ of your portfolio in these triple shorts until the market shows signs of a bottom.

This is especially true if you're using margin or sold puts (which suck up precious equity that the naked eye doesn't necessarily catch).

2.) Keep put options on for insurance! See my Volume 5 E-Guide for more on buying long put options.

In this updated E-Guide, I want to share with you the power of buying 0DTE put options.

If options are like a cheap lottery ticket to gain leverage to the downside, potentially making you millions of dollars in a ***crash***, then buying 0 DTE put options are like lottery tickets on steroids.

Use these in a bind by simply shortening your expirations to the coming week or next.

No need to go 30 days out like with our previous options strategies in Volume 5. So, same strikes (10% away), but closer expirations (0-15 “days to expiration”, or DTE).

But, only use 0DTE put options in a crash, as they decay much more in a typical down market.

At the highs: Add back to triple shorts, box Cornerstone shares, and buy put options.

Buy 0 DTE put options near the lows of the market if no signs of stabilization occur.

3.) SELL put options on long triples at the lows (sell puts on riskier names to lower risk, like with SOXL, TECL, DFEN etc.)

Use sold puts as your natural way to reload into the triple longs and DCA (dollar cost average) on dips in order to rebalance the positions.

You WANT assignment in these. If you don't get assigned, then you just keep the premiums. We earned $50,000-$100,000 in premiums just for clicking our mouse and selling these put options on the indexes.

The account will reflect the growth from these premiums closer to expiration, or if they have a huge move in a short amount of time.

For more on selling put options, see my Volume 6 E-Guide.

4.) Trim long triples on the way back up and switch to YieldBoost!

YieldBoost (YSPY and TQQY) are the same maintenance as the triple longs at Etrade, anyway, and they have protective puts!

This dynamic helps lessen the blow on the way down and helps avoid the decay issues experienced in triples, even though if you hold long enough, the decay issues are minimal, as the triples mentioned here in the beginning of the E-Guide (UPRO, SPXL, TQQQ, and UDOW) have made it back to their old highs, and then some.

5.) Of course, trim long triples on up days to buy more single-leveraged funds, as we mentioned above, not just YieldBoost.

Keep a balance of all dividend funds so that not one takes you down. Try to have NO MORE than 20% in each fund. I go max 10% in each fund, as of now, for what it's worth.

You must have funds like Roundhill and Defiance so that you not only collect the dividends to live FIRE, in any market, but so that you have something to SELL FROM on the way back down to harvest tax losses with and buy 1/3 the triple longs with again.

Single leveraged ETFs like Roundhill and Defiance usually fall less than the market in a correction, and they definitely fall less than the triples, making them advantageous to sell from when deleveraging out of most margin.
You are, consequently, selling at relative gains compared to the market, even though you are taking some losses to do this.

I never want to deleverage all the way out of margin, but if the market calls for it, so be it!

If I buyback 1/3 of the triples on the way down, eventually the margin leverage goes away and my potential to bounce back is even better than before since, again, Defiance and Roundhill don't bounce back well anyway.

These bounces off the lows in the triples, when the market is down 30% from the highs, means a 90% return is what we get off of the lows back to the highs.

We would essentially get a double, just for the market to be at a breakeven at that point- AFTER the 30% rally back to the highs.

In a triple, again, that's 90%, which is basically a double off the lows in these leveraged vehicles, while the market has gone nowhere for the year, and by the way- our margin leverage was mostly, if not completely, gone.

So, effectively there's no risk in these triples except with the indexes, which is not really a risk (historically speaking).

The triples themselves are risky due to their high beta, and higher maintenance.

But as we said earlier, ***you actually preserve equity selling the singles*** (especially the 50% maintenance names like Defiance, Rex, and Roundhill) ***and going 1/3 into the triples from there.***

You also have less risk in the triples than with the singles because, as we postulated earlier, would you rather have 33K in the triples, which is like 100K single leveraged SPY, or 100K in SPY on a 50% market drop?

I'd go with the 33K in triples any day of the week.

Chapter 10

"Nuances of RexShares, Defiance, & Roundhill"

Triples don't give qualifying income, so you have to switch back to the C's, D's (Defiance) and R's (RexShares & Roundhill) after the rally from the lows occur.

RexShares (AIPI and FEPI) and Yieldmax (YMAX and YMAG) bounce back well- and then decay.

So, you trim out of those after the bounce, bring them back to their original position size, and then switch to safer, more broad indexed plays like Roundhill & Defiance.

Here is an SMS text example to my members:

(Unconventional Wealth Ideas) “Trimming $3,500 each of RexShares (AIPI and FEPI) to bring them back to my core $50,000 position. Buying more Roundhill (RH) as previously stated (QDTE & RDTE). RexShares eventually cap their upside, so I’m taking the profit now to switch to RH, who's ETFs are less volatile in a down market”. STOP to end

Defiance sells puts to generate their income (QQQY- Nasdaq, IWMY- Russell 2000, WDTE- S&P 500), and these premiums increase in a down market. They also fall less than the market on down days, usually.

Roundhill sells calls, on the other hand, to juice their dividend yield (XDTE- S&P 500, QDTE- Nasdaq, RDTE- Russell 2000), and their yields generally increase in up markets, since calls appreciate in value as prices rise.

Defiance, and its funds mentioned in this E-Guide, will be changing their structure to calls, apparently, so just keep that in mind.

A reduction in Defiance holdings may be prudent until we are more comfortable with how it reacts to market stimuli.

Chapter 11.

The Magic of Yieldmax

Don't forget about the YIELDMAX MAG 7 drip strategy, and their inverse short hedge strategies.

I like to use Yieldmax for both their bounce back ability off of the lows and their exorbitant yields, especially with the Mag 7 names, which are large portions of the indexes.

You can then hedge them with the inverse short income ETFs like DIPS and CRSH, neutralizing your risk in down markets.

DIPS for NVDY, CRSH for TSLY.

These Yieldmax names just become income-producing machines with risk that is zeroed out, especially when combined with a FNGD triple short, and they “bolt on” the extra income you need to have alongside the low dividend paying triple longs- like UPRO and TQQQ.

Use FNGA/FNGB/FNGU with Yieldmax Mag 7 names to get extra capital gains. Hedge those with FNGD when needed.

When you DRIP Yieldmax you get extra returns, obviously. But, DRIP manually on market dips when using margin, or oversized positioning. This will improve performance and lower interest payments.

Let your position sizes and available for withdrawal tell you when to buy and sell.

Your position sizes should act as your own governor on the way up and down!

When my AFW drops 10%, that means the market dropped 10% and I need to buy (not sell or do nothing).

When my position size falls in YMAG from $10,000 to $9,000, that tells me I need to rebalance $1,000 back into YMAG.

The same goes for the opposite direction.

Rinse and repeat this process during every market correction, big or small.

Chapter 12.

Conclusion

You are now armed and ready with the triple C's. These investment vehicles have never failed me, and with the strategies mentioned in this E-Guide, you are capable of making $1 million dollars over the next 10 years (on $20,000 invested in UPRO and TQQQ, of course).

This $1 million dollar figure is a conservative target, and it assumes the market repeats the performance it had over the last 10 years from 2010- 2020, which seems achievable considering we are now in the AI innovation era.

We are also combining the triples with the C's, sold put options, and these newer dividend funds like Yieldmax, Defiance, Roundhill, YieldBoost, and RexShares, ***on margin***, which will only compound gains further.

I hope you will refer to this E-Guide daily, as I will be doing, in order to stay on the path to the next million.

Please feel free to reach out to me or my members at Discord with any questions you may have.

Godspeed!
